Summary

Northern Beaches Consulting Engineers were engaged by Emma Macindoe Interior Design to prepare a Flood Risk Management report. The purpose of the report is to determine the effects of a proposed development on the existing flooding regime within the development site and neighbouring properties. The development site is located at 44 Kooloora Avenue in Freshwater. The subject site is located within an existing flood zone, however, the area within which the development site is located has not been identified as a flood affected area in any of Council's available land zoning mapping or flood information, and therefore has not been strictly assessed against the Northern Beaches Council (Warringah area) flood controls. The criteria used in this report was established in the Stormwater Pre-DA meeting (SPLM2020/0001) with Northern Beaches Council.

To effectively assess the anticipated flooding effects, a hydraulic model was constructed using DRAINS software to determine the peak flood depth within the subject site up to the 1% Annual Exceedance Probability (AEP) storm event. The hydraulic modelling results were used to determine any potential adverse flooding effects associated with the development up to the 1% AEP storm event.

The development is not expected to cause a net loss of flood storage or adverse flooding effects to neighbouring properties should the recommendations in this report be adopted. The results from the analysis are detailed in the report below.

1. Introduction

Northern Beaches Consulting Engineers were engaged by Emma Macindoe Interior Design to undertake a hydrologic and hydraulic investigation into the effects of proposed carport privacy screening and new boundary fencing development at 44 Kooloora Avenue in Freshwater. The assessment involved analysing localised flooding behaviour within the Freshwater catchment up to the 1% AEP storm event.

Christian Ferry and Michael Wachjo of Northern Beaches Consulting Engineers (NBCE) conducted a site inspection at the above address on 13 November 2019. The site inspection was carried out to both observe and measure the existing drainage infrastructure within the development site and critical elements of Council's stormwater drainage infrastructure within the Freshwater catchment. The premises have been assessed in accordance with the requirements of the Stormwater Pre-DA meeting minutes (SPLM2020/0001) dated 02/07/2020, the Council supplied flood information and the *NSW Government Floodplain Management Manual 2005*.

1.1 Aim

The purpose of this report is to determine the peak flood depth within the subject site up to the 1% AEP storm event within an acceptable design criterion and assess the potential flooding impacts within the development site and neighbouring properties as a result of the proposed works. An analysis was undertaken to assess the extent of flooding envisaged to occur through the subject site and examine strategies to mitigate any impacts from flood waters during heavy rainfall events. Note, the analysis utilised the results of 1% AEP storm event modelling using IFD (Intensity Frequency Duration) design rainfall data based on AR&R 2019 (Australian Rainfall & Runoff) methodology.

The calculations and recommendations presented in this report have been prepared in general accordance with the following policies:

- *Australian Rainfall and Runoff: A Guide to Flood Estimation 2019*
- *NSW Government Floodplain Management Manual 2005*

1.2 Site Characteristics

The 573m² site is located on Kooloora Avenue in Freshwater within the Northern Beaches Council (Warringah) LGA and is bounded by residential properties along the north-eastern, north-western and south-eastern boundaries of the site.

Topographical information indicates that the subject site is located within a flood storage area at the bottom of the Freshwater catchment. The base of the Freshwater catchment forms a localised basin, bounded by the vegetated sand dunes west of the Freshwater Beach foreshore which becomes a temporary flood storage zone in heavy rainfall events. The primary cause of flooding is due to the inadequate hydraulic capacity of the existing Council stormwater drainage infrastructure which discharges to Freshwater beach. The impact of the inadequate discharge capacity is exacerbated when peak storm events occur in conjunction with high tides.

The existing stormwater drainage network consists of a series of pits and pipes which conveys public stormwater from the upstream catchment through to the catchment discharge point at the northern end of the Freshwater Beach foreshore. There are currently 2 x 1650mm & a 450mm diameter Council owned reinforced concrete pipeline (RCP) which extends through the subject property frontage towards Freshwater Beach (refer Appendix B for details). These pipes discharge into 2 x 1800mm diameter pipes which outlet onto the Freshwater Beach foreshore. These outlet pipelines convey collected runoff from the upstream catchment which extends west of 44 Kooloora Avenue up to the crest on McDonald street approximately 1350m away.

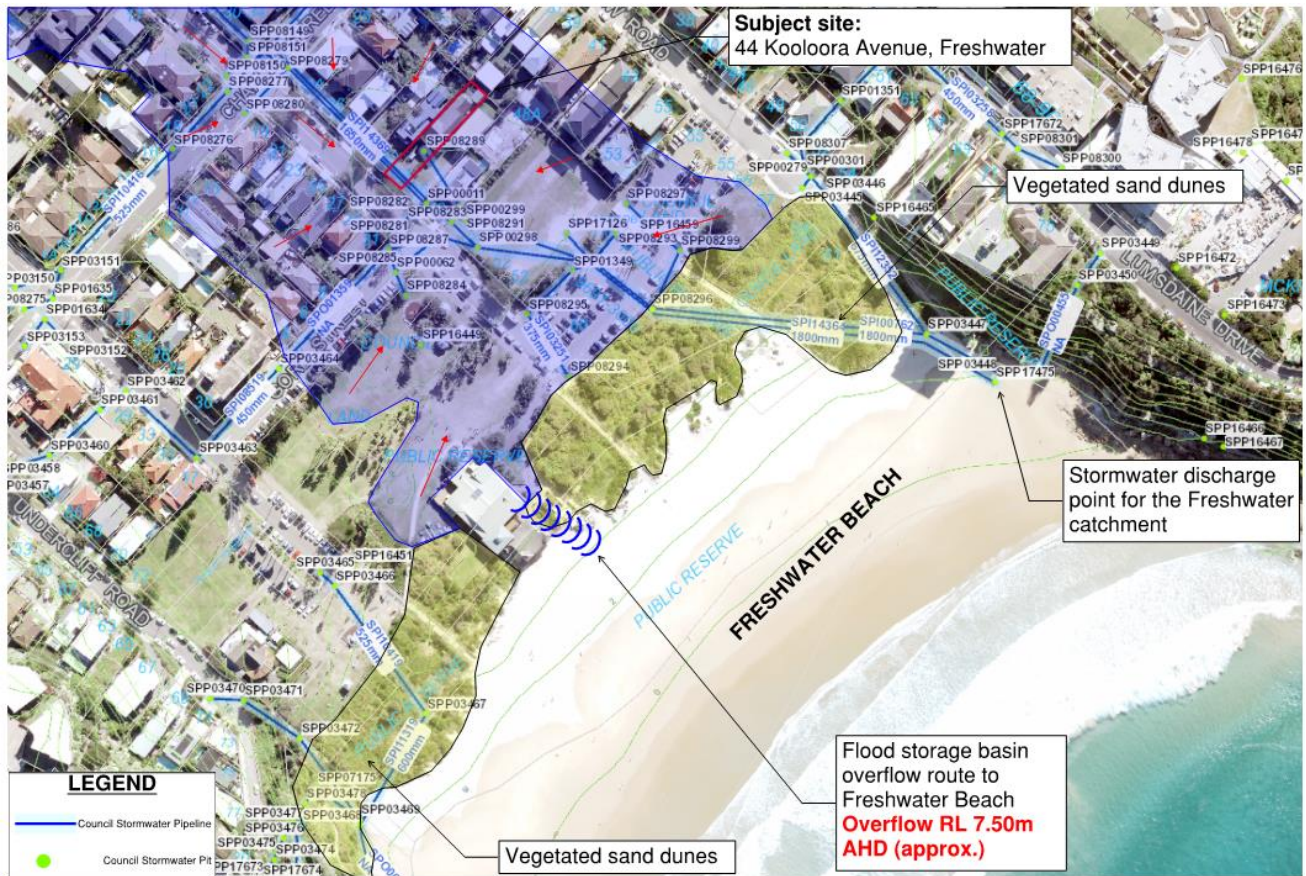

Figure 1 - Subject Site Location and Surroundings. Source: SIX Maps (NSW)

2. Flooding

2.1 Methodology

The flooding extent was modelled using the computer program DRAINS. A combination of LiDAR (Light Detection and Ranging) survey data, survey levels prepared by TTS Total Surveying Solutions and SIX Maps (NSW) government website information were used to estimate the total catchment area. The peak stormwater runoff rates within each of the contributing sub-catchments upstream of the subject site and the resulting flood depth within the flood storage area was modelled in the computer program DRAINS for the 1% AEP storm event.

2.2 Hydraulic Modelling Parameters

Multiple assumptions and parameters were considered in the construction of the hydraulic model. The modelling assumptions and parameters used are based on available survey data and on-site investigations.

2.2.1 Sub-Catchment Assumptions

Five sub-catchments were used in the analysis to effectively determine the flood behaviour within the wider catchment. The following assumptions are based on available survey information and recommended guidelines.

- An impervious ratio of 75% was used for 4 of the upper sub-catchment nodes (refer to Figure 2).
- An impervious ratio of 67% was used for the lower sub-catchment node at the bottom of the freshwater catchment (refer to Figure 2). This catchment also includes large grass park areas at the eastern end of Kooloora avenue.
- A roughness retardance coefficient of 0.012 and 0.33 was used for the impervious and pervious areas, respectively.

2.2.2 Pit and Pipe Blockage Factors

The following assumptions are based on available survey information and accepted guidelines. The below parameters are based upon an approved criterion set by Northern Beaches Council in the Stormwater Pre-Lodgement Meeting Notes (SPLM2020/0001 dated 20/07/2020).

- No blockage factors have been applied to the pipe in the hydraulic model. The velocities through the 2 x 1800mm diameter outlets at Freshwater beach are expected to fall between 3-4m/s during peak storm events. These high velocity rates will facilitate self-cleaning of the pipelines (refer to Appendix D for details).
- A blockage factor of 80% was applied to all sag pits within the hydraulic model.
- A constant outlet water level of 1.475m AHD was used to represent the king tide tailwater condition for the 2 x 1800mm diameter outlets at Freshwater Beach. The king tide level has been conservatively taken as the highest tidal level ever recorded in the Sydney area (refer to Figure 2 below). Source: Manly Hydraulics Laboratory (NSW Government website)

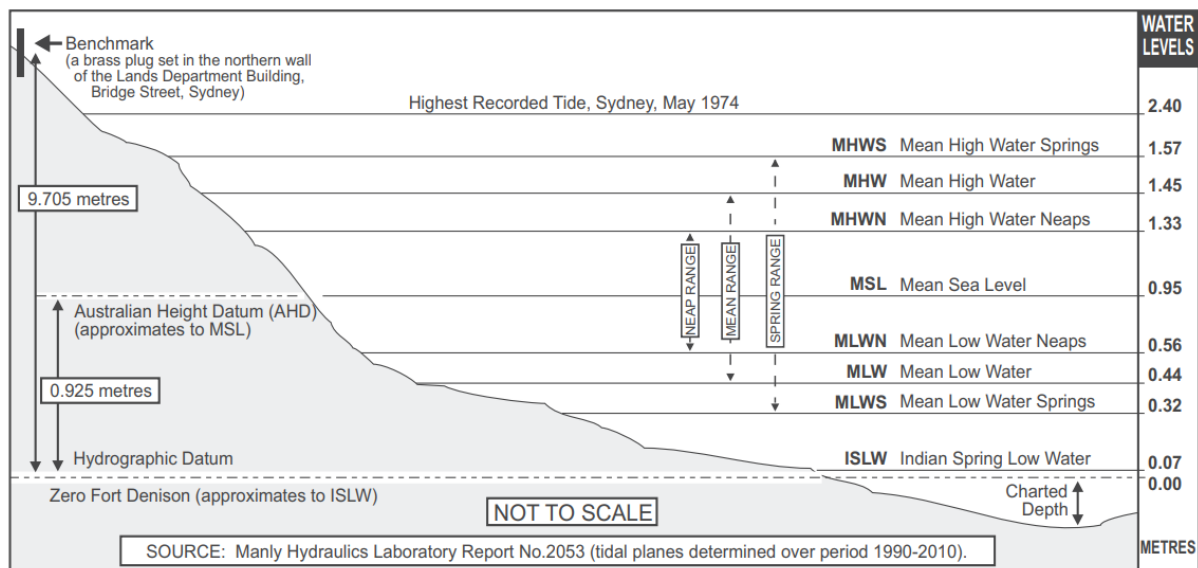

Figure 2 - NSW Tidal Charts (2020). Source: Manly Hydraulics Laboratory (NSW Government website)

2.2.3 Flood Storage Basin Parameters

To effectively represent the flood storage areas within the wider Freshwater catchment, storage basin nodes were used in a hydraulic model to accurately represent each of the critical temporary detention basins within the catchment, as these have a considerable impact on the hydraulic behaviour of stormwater runoff within the wider catchment. For the purpose of this report the following assumptions are made based on the available survey information and on site observations:

- Jacka Park Storage Basin 1 and Jacka Park Storage Basin 2 (Refer Figure 3) are located in Freshwater and are bound by Wyndora Avenue, Eric Street, Glen Street and Oliver Street. The two storage basins at Jacka Park are assumed to collect stormwater runoff from sub catchment A (refer Figure 4).
- Freshwater Storage Basin (Refer Figure 3) is located in Freshwater and bound by Albert Street, Moore Road and Ocean View Road. The Freshwater storage basin is assumed to collect stormwater runoff from sub-catchment E (refer Figure 4) and discharges through the council pipe at Freshwater beach.

Figure 3 - Storage Basin Locations within the Freshwater Catchment. Source: QGIS

2.2 Catchment Analysis

The subject site is located within the Freshwater catchment which conveys stormwater runoff to Freshwater Beach via Council's stormwater drainage infrastructure. The total contributing catchment affecting the subject site was measured in the computer program QGIS 2.18.8 using LiDAR data and is approximately 89.215 Ha.

The contributing catchment consists predominately of low-medium residential development. The catchment extends approximately 1500m upstream and reaches an elevation of approximately 68m AHD. QGIS 2.18.8 was also used to measure the average catchment slope. The manning's roughness 'n' values used for the analysis have been approximated based on observed site conditions (refer Table 1 below). Modelled results from a DRAINS analysis have been used to estimate the peak flow flood depth for the 1% AEP storm event.

Table 1 - Roughness Parameters used for DRAINS

Surface Type	Manning's Roughness (n)
Road / Paving	0.012
Grass	0.33

Five sub-catchments were considered in the analysis to appropriately represent the wider Freshwater catchment. The wider catchment was reduced to five critical sub-catchments for the purpose of providing a more accurate representation of the wider catchment flow behaviour. Each of the sub-catchments are listed below (refer to Figure 4).

- Jacka Park Sub-Catchment (Sub-Catchment A)
- Soldiers Avenue Sub-Catchment (Sub-Catchment B)
- Alfred Street Sub-Catchment (Sub-Catchment C)
- Ocean View Road Sub-Catchment (Sub-Catchment D)
- Freshwater Sub-Catchment (Sub-Catchment E)

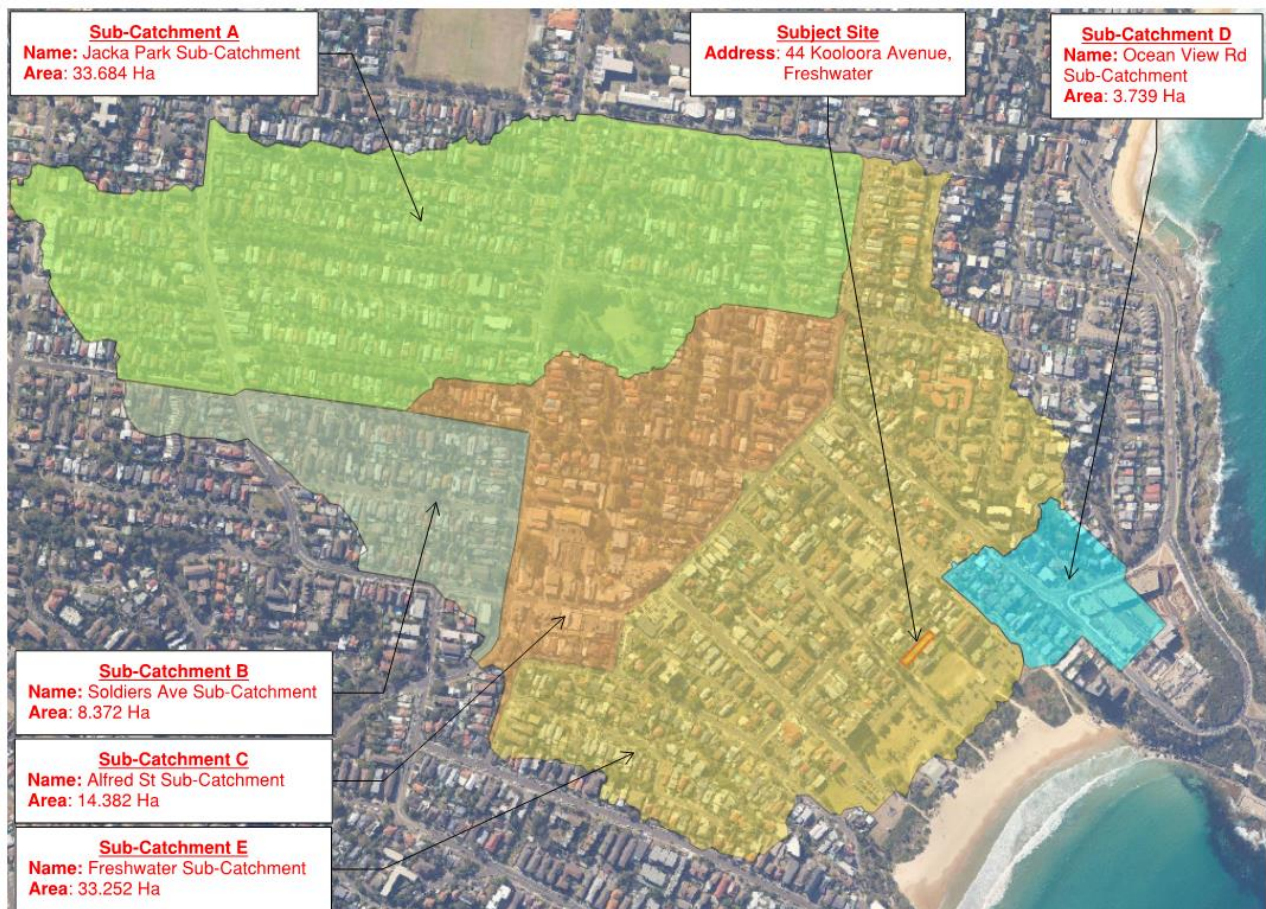

Figure 4 – Critical Sub-Catchments within the Freshwater Catchment. Source: QGIS

3. Analysis & Results

3.1 Peak Flow Results

A DRAINS computation analysis was completed to determine the anticipated runoff through the subject site. The 1% AEP storm event was computed, and the peak runoff rates are shown in Table 2 below:

Table 2 - Catchment Flow Rates for the 1% AEP Storm Event

AEP	Sub-Catchment	Area (Ha)	Piped Flow (m ³ /s)	Overflow (m ³ /s)
1%	A	33.684	6.82	2.52
1%	B	8.372	0.131	4.02
1%	C	14.382	7.06	9.32
1%	D	3.739	2.13	0
1%	E	33.252	20.2	0

For further detail refer Appendix A.

3.2 Flooding Extent

The 1% AEP peak flood depth has been estimated using the computer program DRAINS. The 1% AEP storm event was computed, and the peak flood depths within the Freshwater Storage Basin within the Freshwater sub-catchment are shown in Table 3 below:

Table 3 - Flood Depths for the 1%, 2%, 5% & 0.2EY Storm Events

AEP / EY	Flood Depth (m AHD)
1% AEP	5.05
2% AEP	4.86
5%	4.63
0.2EY	4.20

4. Recommendations

4.1 Carport Privacy Screening

The proposed carport screening has been designed so as to be a minimum 50% open (proposed approx. 60% open) up to the 1% AEP Flood Level (RL 5.05m AHD). The perimeter of the carport is to be restricted from being used for storage and kept clear from obstructions so as to allow flood waters to freely enter the carport. Therefore, the above carport privacy screening is not anticipated to impact the conveyance of flood waters across the site or impact neighbouring properties. Further, the carport privacy screening is to be designed to cater for flood loads up to the FPL and so as to withstand the impact of a floating vehicle up to the 1% AEP flood event. This is to prevent floating vehicles from leaving the site. A velocity of 1m/s can be assumed as the velocity for the 1% AEP.

4.2 Boundary Fencing

The proposed fencing along the boundaries is to be of an open design from natural ground level up to the 1% AEP flood level (5.05m AHD). At least 50% of the fence must be open, with openings a minimum of 75mm x 75mm so that flood waters can flow through unimpeded.

Where the existing boundary fencing is solid masonry wall this can be retained or replaced, however it should not be built up or extended beyond its existing extent.

The fencing is to be certified and/or designed by a civil engineer to withstand hydrostatic forces up to and including the 1% AEP storm event.

4.3 Building Components and Structural Soundness

All new electrical equipment, power points, wiring, fuel lines, sewerage systems or any other service pipes and connections must be waterproofed and/or located above the FPL and conduits must be laid such that they are free draining. New structures located below the FPL are to be adequately flood proofed.

All new development should be designed and constructed of flood compatible materials in accordance with “Reducing Vulnerability of Buildings to Flood Damage: Guidance on Building in Flood Prone Areas”, Hawkesbury-Nepean Floodplain Management Steering Committee (2006).

5. Conclusion

In accordance with accepted engineering practice, NBCE has undertaken a flood study of the stormwater drainage system at 44 Kooloora Avenue in Freshwater and can confirm the accuracy of the calculated results based on the DRAINS modelling. The proposed development will be safeguarded from flooding and will not adversely affect other structures or properties as a result of the proposed development. Please contact the author if further clarification is required.

APPENDIX D

Pipeline Velocity Self-Cleaning Information

Pg 1: Brisbane City Council, “Stormwater Outlets in Parks and Waterways [Guidelines]”, Version 2, 2003, Chapter 3, pg 5

Pg 2: Concrete Pipe Association of Australasia , “Hydraulics of Precast Concrete Conduits”, Reprinted 2012, Pg 42

PERFORMANCE CRITERIA

ACCEPTABLE SOLUTIONS

- Consequences of adverse flooding impacts are investigated for full grate blockage.

A4.6 Detention Storage

Where the public space is also used for stormwater detention storage, the design intents and safety aspects satisfy the requirements of Council's Subdivision and Development Guidelines.

A4.7 Pipe Velocity

The velocity of stormwater flows in pipes or box sections is adequate to maintain self-cleaning, and the velocity prevents scouring and erosion of the conduit especially the invert.

- The desirable minimum design velocities are limited to 1.2 m/s for partial flow and 1.0 m/s for full flow conditions.
- The desirable maximum design velocities are limited to 4.7 m/s for partial flow and 4.0 m/s for full flow conditions (energy dissipation may be required).

A4.8 Outlet Velocity

The average outlet velocity (V_o) for the nominated design discharge (Q_o) is determined. Typically Q_o also corresponds to the design storm event for the pipe. However, for reasons of cost or practicality, it may be necessary to design scour protection for a lower discharge event. The permissible maximum flow velocities (m/s) for the different types of exposed soil immediately downstream of the outlet are given below. These figures assume slope gradient <10%, peak velocities maintained for period less than 6 hours, and good (ie 80%) ground cover. Soil erodibility factor, $K \leq 0.019$ corresponds to low erodibility. $0.020 \leq K \leq 0.045$ and $K > 0.045$ correspond to moderate and high erodibilities respectively.

Permissible maximum flow velocity (m/s)

	Soil erodibility (K) - Low	Moderate	High
Bare soil	0.7	0.5	0.3
Tussock grasses	1.3	0.9	0.5
Other improved perennials	1.6	1.3	0.9
Couch, carpet & other sward-forming grass	2.0	1.8	1.4
Kikuyu grass	2.5	2.2	1.9

Visual intrusion of this stormwater outlet is minimised

4. STORMWATER DRAINAGE

4.1 INTRODUCTION

4.1.1 HEAD LOSSES

The design flow is established as outlined in Section 2, and it is customary in the hydraulic design to assume the pipes flowing full.

The design must take into consideration:

- (i) resistance to flow in conduits
- (ii) losses at inlets and junction pits, bends and other deviations from straight lines of uniform cross section and flow.

Investigations have shown that the latter source of losses can be of greater significance than the energy losses on uniform straight runs, particularly on short lengths of pipeline [4.1, 4.2].

4.1.2 MINIMUM AND MAXIMUM VELOCITIES

Much of the debris entering stormwater drains is heavier than water, and to ensure some measure of self cleansing a minimum velocity of about 0.5 to 1 m/s at full and half full flow or a boundary shear of 1.5 N/m² is recommended [4.1, 4.3]. (Refer also to Section 1.4 and 3.4.4.)

Maximum velocities are discussed in Section 3.4.3. Generally velocities should be kept below 8 m/s if possible.

4.1.3 TOPOGRAPHY

Topographic conditions are significant for the design. In very flat country of minimal fall, layout and details minimising head losses are important in order to avoid excessively deep drains.

In hilly country with steep grades design must consider the possibility of erosion.

4.2 RESISTANCE TO FLOW IN CONDUITS

4.2.1 STRAIGHT DRAINS

For straight, precast concrete pipes or box culverts flowing full with clean water a k value of 0.15 would be appropriate when using the Colebrook-White equation. Having regard to the effect of the debris a value of 0.6 seems reasonable (Figure 1.10) but it must be realised that no tests under these conditions are known to exist.

Figures 1.8 – 1.11 can be used for box culverts (full or part-full flowing) by substituting $4R$ for diameter D , where R is the hydraulic radius for the cross section.

4.2.2 CURVED DRAINS

4.2.2.1 PIPES

It is common for drainage pipelines to be laid straight, but there are circumstances when curves or bends are desirable. Concrete pipes can be laid satisfactorily with deflections at the joints to construct curved pipelines with curve radii of 100–300 pipe diameters. Joint deflections range from 0.6 to 3.0° dependent on diameter. (See Figure 4.1.)

Splayed pipes and bends can be produced to provide curve radii down to about 5 pipe diameters.

Energy losses in curves formed by joint deflections are only slightly higher than those in straight lines and can be treated as such or an extra allowance of

$$0.1 \frac{v^2}{2g}$$

can be added for curve deflections over 20°.

Lobster-back bends show losses with k_b –values ranging up to 1.3 for 90° single splay bends. This and other examples are shown in Table 1.2.

4.2.2.2 BOX CULVERTS

Most box culverts are made with simple butt joints without any claims to watertightness. The joint itself, consequently, offers little scope for joint deflection.
